

MSc - Data Mining

Topic 01 : Module Overview

Part 06 : Top X pandas commands

Dr Bernard Butler and Dr Kieran Murphy

Department of Computing and Mathematics, WIT.
(bbutler@tssg.org and kmurphy@wit.ie)

Spring Semester, 2021

Outline

- Reading data formats
- Computing descriptive statistics
- Processing data by filtering and grouping

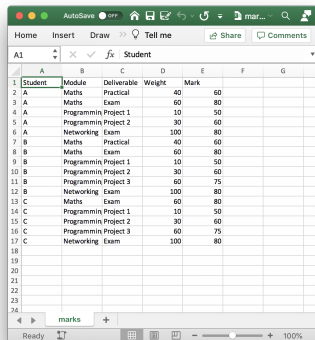

Part I

Introduction

Minimal Dataset

To better understand the various pandas operations we are going use a tiny* dataset based on (fictional) student results. (marks.csv)

In Excel ...

The screenshot shows an Excel spreadsheet with the following data:

	A	B	C	D	E	F	G
1	Student	Module	Deliverable	Weight	Mark		
2	A	Maths	Practical	40	60		
3	A	Maths	Exam	60	80		
4	A	Programmin	Project 1	10	50		
5	A	Programmin	Project 2	30	60		
6	A	Networking	Exam	100	80		
7	B	Maths	Practical	40	60		
8	B	Maths	Exam	60	80		
9	B	Programmin	Project 1	10	50		
10	B	Programmin	Project 2	30	60		
11	B	Programmin	Project 3	60	75		
12	B	Networking	Exam	100	80		
13	C	Maths	Exam	60	80		
14	C	Programmin	Project 1	10	50		
15	C	Programmin	Project 2	30	60		
16	C	Programmin	Project 3	60	75		
17	C	Networking	Exam	100	80		

...or database schema ...

Students

Name ... Other fields

Modules

Name ... Other fields

Deliverables

Name Weight ... Other fields

Grades

Student Module Deliverable Mark

...like to know ...

- Student performance — weighted mark on each module, missing deliverables etc.
- Module performance — number of attempts and average mark.
- Deliverable performance — number of attempts and average mark, predictor of overall module grade, etc.

*Dataset is small enough that you can verify operation results by hand.

Terminology

```
df.head(1000)
```

	Student	Module	Deliverable	Weight	Mark
0	A	Maths	Practical	40	60
1	A	Maths	Exam	60	80
2	A	Programming	Project 1	10	50
3	A	Programming	Project 2	30	60
4	A	Networking	Lab Work	100	80
5	B	Maths	Practical	40	60
6	B	Maths	Exam	60	80
7	B	Programming	Project 1	10	50
8	B	Programming	Project 2	30	60

10	B	Networking	Project	100	80
11	C	Maths	Exam	60	80
12	C	Programming	Project 1	10	50
13	C	Programming	Project 2	30	60
14	C	Programming	Project 3	60	75
15	C	Networking	Lab Work	100	80

- A **DataFrame** is a table of data values.
 - `df = pd.read_csv("marks.csv")`
- A **Series** is a list of data values — typically columns in a dataframe. We can access an individual column using
 - `df.Deliverable` (dot notation)
 - `df["Deliverable"]` (dict notation)
 - `df.iloc[:,2]` (numpy, index notation)
- The **index** is a special column whose values can be used to access rows — rather using row number.
 - The default index is equal to the row number.

Terminology

```
df.head(1000)
```

	Student	Module	Deliverable	Weight	Mark
0	A	Maths	Practical	40	60

 - The default index is equal to the row number.

Part II

Input and Output

Setup

Minimal

We begin every data mining project with importing the three core data science packages:

```
1 import numpy as np
2 import pandas as pd
3 import matplotlib.pyplot as plt
4 plt.style.use('seaborn-darkgrid')
```

numpy — fast array operations
pandas — data manipulation
matplotlib — visualisation

- We give modules nicknames (np, pd, ...) to simplify their later use, and we access properties/functions of a package using the dot notation (np.max, pd.DataFrame, ...).

Extra

```
1 import seaborn as sns
2 import statsmodels.api as sm
3
4 pd.set_option('display.max_columns', 500)
5 pd.set_option('display.width', 1000)
```

seaborn — statistical visualisation
statsmodels — statistical data exploration
pandas options to show all columns for wider datasets

Reading data from a CSV file

Pandas supports a huge variety of input/output formats so best approach is to focus on what is needed to process the given data and verify input. Our marks dataset is in CSV format so we start with

```
1 import numpy as np
2 import pandas as pd
3 import matplotlib.pyplot as plt
4 plt.style.use('seaborn-darkgrid')
```

and input using

```
1 df = pd.read_csv('marks.csv', sep=',')
2 print(df.shape)
3 df.head()
```

	Student	Module	Deliverable	Weight	Mark
0	A	Maths	Practical	40	60
1	A	Maths	Exam	60	80
2	A	Programming	Project 1	10	50
3	A	Programming	Project 2	30	60
4	A	Networking	Lab Work	100	80

Always verify input by checking dataset dimensions and looking at some rows!!!

Datatypes

Pandas data types:

- **object** — used for text or mixed numeric and non-numeric values.
- **int64** — integer values,
 - Does not support missing values, so an int column containing at least one missing value will automatically be converted to float.
- **float64** — floating point numbers.
- **bool** — True/False values
- **datetime64** — date and time values
- **category** — Finite (typically small) list of text values

```
Student      object
Module       object
Deliverable  object
Weight       int64
Mark         int64
dtype: object
```

```
1 df.dtypes
```

Regularly verifying datatypes is vital[†] :

- Operations differ based on datatype, eg, '+' concatenate strings but adds numerical values.
- Datatype can change based on results, eg, int converts to float due to missing values.

[†]Google "Detecting Excel's gene auto-conversions."

Datatypes

Pandas data types:

- Datatype can change based on results, eg, int converts to float due to missing values.

[†]Google "Detecting Excel's gene auto-conversions."

Datatypes — Converting

We will deal with modifying and creating new columns later, but while we are on datatypes, we will look at changing datatype ...

Using the Series function `astype`

```
1 df["Weight"] = df["Weight"].astype('float')
2 df["Weight"].dtype
```

`dtype('float64')`

- New datatype is required argument — 'int', 'float', 'str', 'object', 'category', etc.
- Simple, but fragile if data conversion is possible.

or using pandas function `to_numeric`

```
1 df["Weight"] = pd.to_numeric(df["Weight"])
2 df["Weight"].dtype
```

`dtype('float64')`

- More powerful, can specify what to do in cases where the conversion fails etc
- Have functions `to_numeric`, `to_datetime`, and `to_timedelta`.

Datatypes — Converting

We will deal with modifying and creating new columns later, but while we are on datatypes, we will look at changing datatype ...

Using the Series function `astype`

```
1 df["Weight"] = df["Weight"].astype('float')
2 df["Weight"].dtype
```

`dtype('float64')`

- New datatype is required argument — `'int'`, `'float'`, `'str'`, `'object'`, `'category'`, etc.
- Simple, but fragile if data conversion is possible.

or using pandas function `to_numeric`

```
1 df["Weight"] = pd.to_numeric(df["Weight"])
2 df["Weight"].dtype
```

`dtype('float64')`

- More powerful, can specify what to do in cases where the conversion fails etc
- Have functions `to_numeric`, `to_datetime`, and `to_timedelta`.

Datatypes — Converting

We will deal with modifying and creating new columns later, but while we are on datatypes, we will look at changing datatype ...

➤ Using the Series function `astype`

```
1 df["Weight"] = df["Weight"].astype('float')
2 df["Weight"].dtype
```

`dtype('float64')`

- New datatype is required argument — `'int'`, `'float'`, `'str'`, `'object'`, `'category'`, etc.
- Simple, but fragile if data conversion is possible.

➤ or using pandas function `to_numeric`

```
1 df["Weight"] = pd.to_numeric(df["Weight"])
2 df["Weight"].dtype
```

`dtype('float64')`

- More powerful, can specify what to do in cases where the conversion fails etc
- Have functions `to_numeric`, `to_datetime`, and `to_timedelta`.

Missing Values

Identifying and dealing with missing values is critical step in data preparation. What should you do? delete rows containing missing values? or impute then?

Here we will just look at identifying missing values.

```
df.isna()
```

	Student	Module	Deliverable	Weight	Mark
0	False	False	False	False	False
1	False	False	False	False	False
2	False	False	False	False	False
3	False	False	False	False	False
4	False	False	False	False	False
5	False	False	False	False	False
6	False	False	False	False	False
7	False	False	False	False	False
8	False	False	False	False	False
9	False	False	False	False	False
10	False	False	False	False	False
11	False	False	False	False	False
12	False	False	False	False	False
13	False	False	False	False	False
14	False	False	False	False	False
15	False	False	False	False	False

```
df.isna().sum()
```

```
Student      0  
Module       0  
Deliverable  0  
Weight       0  
Mark         0  
dtype: int64
```

```
df.isna().sum().sum()
```

```
0
```

- Use dataframe function `fillna` to replace missing values.
- Recall False and True map to 0 and 1 respectively.
- Use `df.isna().sum(axis=1)` to sum along rows.

Output

Saving dataframe to CSV is straightforward (I rarely include the (default) index when saving datasets).

```
df.to_csv('marks_2.csv', index=False)
```

- CSV has become the default file format in Data Mining application especially for 'informal' datasets.
 - ✓ human readable, easy to generate / parse (if correct).
 - ✗ Can be highly redundant, slow to input/output.
 - ✗ No meta information.
- Other formats are better for speed and resulting file size and for saving meta data not supported by CSV (such as columns datatypes, category information, etc).

9	B	Programming	Project 3	60	75

```
criteria = ((df.Mark<50) & (df.Module=='Maths')) | ((df.Mark<70) & (df.Module!='Maths'))
columns = ['Module', 'Student', 'Mark']

df.loc[criteria, columns]
```

More complicated example

I prefer to define row selection criteria, and the column list and order, separately to the `loc` statement.

Student Module		Deliverable Weight Mark			
0	A	Maths	Practical	40	60
1	A	Maths	Exam	60	80
2	A	Programming	Project 1	10	50
3	A	Programming	Project 2	30	60
4	A	Networking	Lab Work	100	80
5	B	Maths	Practical	40	60
6	B	Maths	Exam	60	80
7	B	Programming	Project 1	10	50
8	B	Programming	Project 2	30	60
9	B	Programming	Project 3	60	75

Student Module		Deliverable Weight Mark

columns = ['Module', 'Student', 'Mark']
```

```
df.loc[criteria, columns]
```

Sampling

The `sample` function selects a random subset of the dataframe rows.

- Either specify the number of rows (as an integer) or fraction of the data (as a float).
- Can set the seed using `random_state` parameter for reproducible samples.

	Student	Module	Deliverable	Weight	Mark
0	A	Maths	Practical	40	60

Part IV

Sorting

Sorting

A pandas dataframe has two sorting operations:

- `sort_index()` orders rows based on current index.
- `sort_values(COLUMNS)` orders rows based on single column or list of columns.

Two important modifications:

- By default, the sort order is in ascending. Set parameter `ascending=False` to reverse this.
- By default, a new dataframe is returned with desired sort order, set parameter `inplace=True` to update current dataframe instead (then no output is generated).

	Student	Module	Deliverable	Weight	Mark
0	A	Maths	Practical	40	60
1	A	Maths	Exam	60	80
2	A	Programming	Project 1	10	50
3	A	Programming	Project 2		
4	A	Networking	Lab Work		
5	B	Maths	Practical	40	60
6	B	Maths	Exam	60	80
7	B	Programming	Project 1	10	50
8	B	Programming	Project 2	30	60
9	B	Programming	Project 3	60	75
10	B	Networking	Project	100	80
11	C	Maths	Exam	60	80
12	C	Programming	Project 1	10	50

```
df.sort_values(['Module', 'Deliverable'])
```

Sorting

A pandas dataframe has two sorting operations:

- `sort_index()` orders rows based on current index.
- `sort_values(COLUMNS)` orders rows based on single column or list of columns.

Two important modifications:

- By default, the sort order is in ascending. Set parameter `ascending=False` to reverse this.
- By default, a new dataframe is returned with desired sort order, set parameter `inplace=True` to update current dataframe instead (then no output is generated).

	Student	Module	Deliverable	Weight	Mark

7	B	Programming	Project 1	10	50
12	C	Programming	Project 1	10	50
3	A	Programming	Project 2	30	60
8	B	Programming	Project 2	30	60

Part V

Defining New Columns

Defining new columns — row-wise operation

We want to compute the weighted mark for each module for each student. Two steps:

- Create column, `W_Mark`, to store the weighted mark for each deliverable. This is a row by row calculation — only need data in current row to compute the result.
- Create column, `M_Mark`, to store the module mark for each student. This is a group calculation — need all rows for that student and module to compute the result.

	Student	Module	Deliverable	Weight	Mark
1	A	Maths	Exam	60	80
6	B	Maths	Exam	60	80
11	C	Maths	Exam	60	80
0	A	Maths	Practical	40	60
5	B	Maths	Practical	40	60
4	A	Networking	Lab Work	10	80
15	C	Networking	Lab Work	100	80
10	B	Networking	Project	100	80
2	A	Programming	Project 1	10	50
7	B	Programming	Project 1	10	50
12	C	Programming	Project 1	10	50
3	A	Programming	Project 2	30	60
8	B	Programming	Project 2	30	60
13	C	Programming	Project 2	30	60
9	B	Programming	Project 3	60	75
14	C	Programming	Project 3	60	75

```
df['W_Mark'] = df.Weight * df.Mark // 100
```

Need to use dict notation (not dot notation) when defining a new column.

Defining new columns — row-wise operation

We want to compute the weighted mark for each module for each student. Two steps:

- Create column, `W_Mark`, to store the weighted mark for each deliverable. This is a row by row calculation — only need data in current row to compute the result.
- Create column, `M_Mark`, to store the module mark for each student. This is a group calculation — need all rows for that student and module to compute the result.

	Student	Module	Deliverable	Weight	Mark
1	A	Maths	Exam	60	80
6	B	Maths	Exam	60	80
11	C	Maths	Exam	60	80
0	A	Maths	Practical	40	60
5	B	Maths	Practical	40	60
4	A	Networking	Lab Work	100	80
15	C	Networking	Lab Work	100	80
10	B	Networking	Project	100	80
2	A	Programming	Project 1	10	50
7	B	Programming	Project 1	10	50
12	C	Programming	Project 1	10	50
3	A	Programming	Project 2	30	60
8	B	Programming	Project 2	30	60
13	C	Programming	Project 2	30	60
9	B	Programming	Project 3	60	75
14	C	Programming	Project 3	60	75

```
df['W_Mark'] = df.Weight * df.Mark // 100
```

Need to use dict notation (not dot notation) when defining a new column.

	Student	Module	Deliverable	Weight	Mark	W_Mark
1	A	Maths	Exam	60	80	48
6	B	Maths	Exam	60	80	48
11	C	Maths	Exam	60	80	48
0	A	Maths	Practical	40	60	24
5	B	Maths	Practical	40	60	24
4	A	Networking	Lab Work	100	80	80
15	C	Networking	Lab Work	100	80	80
10	B	Networking	Project	100	80	80
2	A	Programming	Project 1	10	50	5
7	B	Programming	Project 1	10	50	5
12	C	Programming	Project 1	10	50	5
3	A	Programming	Project 2	30	60	18
8	B	Programming	Project 2	30	60	18
13	C	Programming	Project 2	30	60	18
9	B	Programming	Project 3	60	75	45
14	C	Programming	Project 3	60	75	45

Defining new columns — group aggregate result

I

- Create column, `W_Mark`, to store the weighted mark for each deliverable. This is a row by row calculation — only need data in current row to compute the result.
- Create column, `M_Mark`, to store the module mark for each student. This is a group calculation — need all rows for that student and module to compute the result.

columns to group on output cols aggregate
`df.groupby(['Student', 'Module'])['W_Mark'].sum()`

	Student	Module	Deliverable	Weight	Mark	W_Mark
1	A	Maths	Exam	60	80	48
6	B	Maths	Exam	60	80	48
11	C	Maths	Exam	60	80	48
0	A	Maths	Practical	40	60	24
5	B	Maths	Practical	40	60	24
4	A	Networking	Lab Work	100	80	80
15	C	Networking	Lab Work	100	80	80
10	B	Networking	Project	100	80	80
2	A	Programming	Project 1	10	50	5
7	B	Programming	Project 1	10	50	5
12	C	Programming	Project 1	10	50	5
3	A	Programming	Project 2	30	60	18
8	B	Programming	Project 2	30	60	18
13	C	Programming	Project 2	30	60	18
9	B	Programming	Project 3	60	75	45
14	C	Programming	Project 3	60	75	45

Result has multi-level index, need to use `reset_index` to revert to default index

Defining new columns — group aggregate result

I

- Create column, W_Mark, to store the weighted mark for each deliverable. This is a row by row calculation — only need data in current row to compute the result.
- Create column, M_Mark, to store the module mark for each student. This is a group calculation — need all rows for that student and module to compute the result.

columns to group on output cols aggregate
`df.groupby(['Student', 'Module'])['W_Mark'].sum()`

9	B	Programming	Project 3	60	75	45
14	C	Programming	Project 3	60	75	45

This is the required result and we can save this to a new dataframe. However, we often want to put this into our original dataframe as an extra column. Only problem we have is different rows so can't just assign to a new column — need to use transform function.

	Student	Module	W_Mark
0	A	Maths	72
1	A	Networking	80
2	A	Programming	23
3	B	Maths	72
4	B	Networking	80

9	B	Programming	Project 3	60	75	45	68
14	C	Programming	Project 3	60	75	45	68

The transform broadcasts the result for each group over every row in that group.

Part VI

Review Exercises

Review Exercises

Generate the following reports:

- 1 Number of deliverables by each student.
- 2 List and rank deliverables by grade.
- 3 Top 2 deliverables (by grade).
- 4 Top 2 module (by average grade).
- 5 Top 2 modules (by minimum grade).
- 6 Modules (by minimum grade).

(value_counts, or groupby and count)

(sort_values, rank)

Harder exercises (new functions)

- 1 List which students missed which deliverables.

(pivot, melt)
